Worksheet & Answer Key

Carbon compounds undergo addition reactions when they react with unsaturated molecules, such as alkynes or alkenes. These reactions involve the addition of a functional group to the carbon chain, which can lead to the formation of new bonds and altered chemical properties. For example, the reaction between ethene and chlorine gas forms chloroethene through an addition process.

Word Bank:

alkenes, chlorine, unsaturated, functional, reactions, carbon, chain, formed

Fill in the blanks:

1. Carbon compounds undergo addition reactions when they react with unsaturated molecules, such as alkynes or _____.

2. These reactions involve the addition of a _____ group to the carbon _____.

3. For example, the reaction between ethene and _____ gas forms chloroethene through an addition process.

4. The reaction between ethene and _____ gas forms chloroethene through an addition process.

5. Carbon compounds undergo addition reactions when they react with unsaturated molecules, such as ____ or alkenes.

6. These reactions involve the formation of new _____ and altered chemical properties.

7. For example, the reaction between _____ and chlorine gas forms chloroethene through an addition process.

8. The reaction between _____ and chlorine gas forms chloroethene through an addition process.

9. Carbon compounds undergo addition reactions when they react with unsaturated molecules, such as alkynes or ____.

■ Answer Key (for teachers only):

1. alkenes
2. chlorine
3. unsaturated
4. functional
5. reactions
6. carbon
7. chain
8. formed
